

Missing Production Migrations — TSCopier

Date checked: 2026-08-16 **Environment:** Production
(sxxkpcovbyaficvtkpsdo) **Status:** Verified missing by checking the database directly (not just the migration list)

Summary

Production is **missing 4 database changes** that staging already has.

Two of them are a **live problem**: the app code is already running on production, and it writes to a place in the database that was never created. Right now, when a user clicks “Report” on a trade (or asks the assistant to report a trade), the action fails with an error.

The other two are **prep work for a feature that is switched off**. They are safe to wait.

#	Change	On prod?	Priority	Why
		×		
1	20260810000000_trade_reports	Missing	HIGH	The table where trade reports are stored — live code writes to it
		×		
2	20260816000000_trade_reports_signal_id	Missing	HIGH	Adds a link from a report

#	Change	On prod?	Priority	Why
				back to its signal; needs #1 first
3	20260730120000_layering_modes_foundation	Missing	MEDIUM	Extra storage space for a future (off) feature
4	20260731120000_layering_plans	Missing	MEDIUM	The future feature's main storage; needs #3 first
Production already has the broker-channel limits change (20260805082647), verified working since 2026-08-05.				

What each change does

1. Trade reports table — HIGH priority (live problem)

What it does: Creates the `trade_reports` table — the place where user complaints about trades (“wrong entry”, “wrong stop-loss”, “not executed”, etc.) are stored for support staff to review. Each report keeps a snapshot of the trade (symbol, direction, ticket, broker, entry price, stop-loss, take-profit, lot size), plus a category, a reason, and a status (open or resolved). Users can only see and file their **own** reports.

Where it's used in the code: - **Manual report button:** `src/components/trades/ReportTradeModal.tsx` — saves the report from the trade detail modal. - **Assistant report tool:** `supabase/functions/assistant-chat/index.ts` — the assistant's `report_trade` tool saves a report the same way.

What happens without it: Every attempt to file a report fails with ERROR 42P01: relation "trade_reports" does not exist. This is a real, user-facing defect on prod.

2. Link reports to their signal — HIGH priority

What it does: Adds a `signal_id` column to each trade report, so a report can point back to the signal it came from. This matters for **skipped or non-actionable** trades — the ones with no symbol or ticket — because the assistant can now file reports on those too, and support needs to know which signal the report was about. The column is optional and old reports are untouched.

Where it's used in the code: - Writer: `supabase/functions/assistant-chat/index.ts (report_trade)` — saves the `signal_id` when the assistant files a report, so it can be traced back to the original signal. - Nothing else reads this column; it exists for support traceability.

What happens without it: Once change #1 is applied, reports still save — they just can't be linked back to their signal.

3. Storage space for future layering modes — MEDIUM (feature is off)

What it does: Adds two empty boxes to the table that holds the ladder of pending orders for range trades: `layer_plan_id` (which plan a waiting order belongs to) and `layer_plan_metadata` (extra details about that link). It also adds an index so lookups are fast. Existing orders are untouched and behave exactly as before.

Where it's used in the code: - Writers: `worker/src/manualPlanning/layeringPlanPersistence.ts` fills these boxes on the waiting orders; `worker/src/layeringPlanLifecycle.ts` and `worker/src/tradeExecutor/layeringModeBrokerPending.ts` read them as the orders move through execution.

What happens without it: The worker code already writes and reads these boxes. On prod the boxes don't exist, so those writes fail **the moment** the feature is switched on. While the feature stays off, nothing breaks.

4. Main storage for the future layering feature — MEDIUM (feature is off)

What it does: Creates the `layering_plans` table — the saved plan for a range-trade ladder (which mode, its lifecycle status, the frozen calculator details, and a fingerprint to spot duplicate plans). It also adds the `activate_layering_plan` function that turns a saved plan into real waiting orders, plus a set of empty boxes on the waiting orders for tracking each order through the broker (submitted, waiting, confirmed, cancelled). Internal-only — users have no access to this table.

Needs #3 first: its index on `range_pending_legs(layer_plan_id, step_idx)` requires the `layer_plan_id` column added in change #3.

Where it's used in the code: - **Writer:** `worker/src/manualPlanning/layeringPlanPersistence.ts` — saves the plan and calls `activate_layering_plan(...)` to turn it into waiting orders. - **Readers:** `worker/src/tradeExecutor/layeringModeBrokerPending.ts` (submits orders and records their broker status), `layeringModeBrokerPendingRecovery.ts` (reads the saved plan to resume after a restart), `layeringPlanLifecycle.ts`, and `worker/src/virtualPendingMonitor.ts`.

What happens without it: With no table on prod, saving a plan fails; with no status boxes, tracking submitted orders fails; and if the worker restarts mid-trade, there is no saved plan to read, so it can't continue. Pure additive — nothing runs this feature until it's switched on, and it's behind kill-switch flags (`LAYERING_MODES_EXECUTION_ENABLED`, `LAYERING_MODES_PREPARE_ONLY`) that only allowlist staging accounts can use.

How we know this

We ran the same 5 checks against **staging** (which has the changes) and **prod**:

Check	Staging (has it)	Prod
Does the <code>trade_reports</code> table exist?	Yes	No
	Yes	None

Check	Staging (has it)	Prod
Any tables matching “%report%”?		
Any tables matching “%trade_report%”?	Yes	None
Changes registered in the migration list?	Both versions	None
Can we count the rows in trade_reports?	Yes (8 rows)	Error: table does not exist

Prod also fails the checks for the layering changes: no layering_plans table, no layer_plan_id / layer_plan_metadata / broker_client_reference columns on the waiting orders, and no layering guard triggers.

Because staging passes the same checks, we know the checking method is sound — the prod failures are real.

What to do

Recommended: apply changes #1 and #2 to prod now — they fix the live trade-report failure for both the manual button and the assistant. Steps:

1. Run the SQL against the prod database (via the Supabase Management API, using an admin token).
2. Register the changes in the supabase_migrations list so the migration tracker knows they were applied.
3. Re-check that the table, column, and indexes exist.

Decision needed: whether to also apply #3 and #4 to prod now, or wait until the layering feature is scheduled. They’re safe either way — they don’t change anything until the feature is switched on.

Also pending (code, not a database change): redeploy the assistant-chat edge function to staging then prod with the skipped-trade report_trade fix (the code is committed; the function is deployed manually).

Status update — 2026-08-17

- All four migration files (incl. #1 and #2) are now **committed to the repo** on the staging and dev branches and pushed to origin + upstream, so they can no longer be lost.
- The assistant-chat edge function change (skipped / non-actionable report_trade with signal_id, plus the “last trade” few-shot guidance) and the clickable assistant trade-detail card (opens the copier-log detail modal) are on the same branches.
- **Still required — apply + register #1 and #2 on prod (sxkpcovbyaficvtkpsdo) before deploying the updated assistant-chat function.** Then deploy the function to staging → prod. If the column does not exist when the function ships, every report_trade insert fails with column "signal_id" does not exist.
- Re-check prod afterwards: to_regclass('public.trade_reports') should return trade_reports and trade_reports.signal_id should exist.

Plain English: TSCopier's production database is missing 4 things. Two of them (the trade-reports table) mean users can't file a trade complaint right now — the button errors out. The other two are behind-the-scenes prep for a future feature that isn't turned on yet. Staging has all 4.
